## OVERVIEW

Opioid misuse especially by injection is associated with mortality and is a common cause of HIV transmission. Methadone replacement therapy is used to reduce dependence on opioids. Methadone has high pharmacokinetic (PK) variability, and it is a racemic mixture of Rand S-methadone with differing activities and routes of elimination. These factors make it challenging to dose. R- and S-methadone total (bound plus unbound) and unbound (the active compounds) concentrations have been collected in HIV+ and HIV- patients to elucidate dose-exposure relationships and examine differences between HIV+ and HIV- patients. Nonlinear mixed-effect modeling (NLMEM) is useful to link patient-specific characteristics to elimination processes and therefore drug exposure. Statistical challenges include a relatively complex pharmacokinetic model, limited concentration data in each patient, and since the total and unbound R- and Smethadone concentrations are obtained at the same time, the analysis should account for inherent correlations among the 4 compounds. While NLMEM can address these concerns using Bayesian estimation methods, the methodological challenge is the substantial computing power necessary to implement these pharmacostatistical models. The aim of this study was to identify patient characteristics and assess pharmacokinetic differences in clearance, volume of distribution, protein binding, and bioavailability

## METHODS

A total of 7908 observations (309 subjects) were obtained as trough and peak steady-state concentrations for unbound and total R- and Smethadone. A NLMEM approach was conducted to simultaneously analyze the 4 compounds using Bayesian estimation method with interaction in NONMEM v7.5 (ICON plc development). Based on bayes theorem

$$p(\Phi|y) \propto p(y|\Phi)p(\Phi) \tag{1}$$

The posterior distribution of  $\Phi$  given the observed data  $y$  is proportional to the conditional likelihood function of the data  $y$  given  $\Phi$  and the prior distribution of  $\Phi$ ; Where  $\Phi$  is a vector of individual pharmacokinetic parameters.

The pharmacokinetic parameters  $\Phi$  used for estimation are unbound drug clearance ( $CL_U$ ), unbound volume of distribution ( $V_U$ ) and Fraction unbound ( $F_U$ ) for the unbound R and S methadone, thus we have 6 set of main pharmacokinetic parameters. Patient characteristics such as body weight and HIV status were implemented to identify to describe the variability in PK parameters and identify the difference in PK between HIV +/- patients. Additional covariates such as concomitant use of antiretrovirals such as Efavrizn and NVP were used based on a prior knowledge.

Assuming that the unbound R and S methadone data can be described using a multidose one-compartment model with first-order absorption and first-order elimination,  $f(\cdot)$ , then:

$$C_u(t) := f(\Phi, x_i, t_{i,j}) = \frac{F \cdot D \cdot k_a}{V_U(k_a - (CL_U/V_U))} \left( \frac{\exp(-(CL_U/V_U)t_{i,j})}{1 - \exp(-(CL_U/V_U)\tau)} - \frac{\exp(-k_a t_{i,j})}{1 - \exp(-k_a \tau)} \right) \tag{2}$$

The total R/S methadone,  $g(\cdot)$ , can be obtained using the Fraction of unbound ( $F_U$ ):

$$C_{tot}(t) := g(\Phi, x_i, t_{i,j}) = \frac{C_u(t)}{F_U} \tag{3}$$

A proportional error model was used to describe the observed data:

$$y_{i,j,U} = f(\Phi, x_i, t_{i,j}) + f(\Phi, x_i, t_{i,j})\epsilon_{i,j}$$

$$y_{i,j,T} = g(\Phi, x_i, t_{i,j}) + f(\Phi, x_i, t_{i,j})\epsilon_{i,j}$$

Where  $y$  presents the observed concentration for the  $i^{th}$  concentration and  $j^{th}$  subject;  $\epsilon$  is a multivariate random variable with mean vector of zeros and variance matrix of  $\Sigma$ .

A “warm-up” estimation step was done using stochastic approximation expectation-maximization (SAEM) algorithm to evaluate a possible value for prior distribution. The results from SAEM were used as uninformative prior distribution to allow more relaxed Bayesian estimation.

Generally, Monte-Carlo Markov chains (MCMC) samples in Bayesian analysis can be highly correlated, therefore, three independent sets of initial values were generated using MCMC sampled from the prior distribution. For each chain Bayesian estimation with interaction was conducted with 6000 samples in a burn-in phase and 8000 samples for sampling phase.

This current analysis was carried out using Minnesota Supercomputer Institute resources. NONMEM 7.5 was used in model estimation and Python 3.8 for postprocessing (Data visualization).

## RESULTS

Table 1. Final parameter estimates for unbound R/S methadone model

Parameter	Units	Estimate	95% CI
R-methadone			
$CL_U$	(L/hr/70kg)	383.2	(317.3 - 466.3)

Table 2. Correlation matrix of the random effects (Lower triangle); The upper table provides the full variance- covariance matrix expressed as BSV correlations; The lower panel present residual unexplained correlations (SIGMA). Correlation of interest are color coded (maroon: within the same enantiomer, gold: with different enantiomer)

	$\omega_{CL_U,R}$	$\omega_{V_U,R}$	$\omega_{F_U,R}$	$\omega_{CL_U,S}$	$\omega_{V_U,S}$	$\omega_{F_U,S}$
$\omega_{CL_U,R}$	1.0					
$\omega_{V_U,R}$	0.69	1.0				
$\omega_{F_U,R}$	-0.67	-0.72	1.0			
$\omega_{CL_U,S}$	0.74	0.87	-0.64	1.0		
$\omega_{V_U,S}$	0.72	0.82	-0.67	0.70	1.0	
$\omega_{F_U,S}$	-0.65	-0.71	-0.98	-0.65	-0.66	1.0

## CONCLUSION

- 1 Patients with HIV+ tend to have a significantly lower protein binding fractions of both unbound R/S methadone compared to HIV- patients. This means that when comparing total concentrations, active drug exposure ( $C_u$ ) will be higher than expected in HIV+ patients compared to HIV- patients.
- 2 The apparent bioavailability ( $F$ ) is decreased in HIV+ patients. These results are not unexpected as there are known pathophysiological changes in the gut with HIV infection. A decrease in drug absorption suggest higher doses might be needed in HIV+ patients.
- 3 A high correlation was noticed between S- and R-methadone for both the total and unbound concentrations. While it is expected to be high, it has not been previously quantified.
- 4 Taking either efavirenz or nevirapine increased unbound R-methadone CL/F 220%
- 5 Nevirapine and efavirenz increased unbound S-methadone CL/F by 404% and 273%, respectively.
- 6 Variants in NR1I3 increased unbound R- and S-methadone CL/F by approximately 20% only in patients taking efavirenz.
